Cytometer Characterization and Optimization Using the QuantiFlash

Chairmen: Svoboda J., Janda J. (Prague, CZ)

Instrument Characterization

One of the well-known methods to characterize flow cytometers uses the following parameters to compare machines against each other: detection efficiency Q and the signal background B. The use of the quantiFlash to easily perform this evaluation will be demonstrated by our collaborator Toralf Kaiser.

Apart from this, other critical parameters that become easily accessible by using the quantiFlash. We want to point out how to measure

- the signal to noise ratio (SNR) and dynamic detection range (DNR)
- the optimal PMT gain (voltage) dependent on SNR and DNR

Cross-Channel Gain Calibration

Understanding how the gain of a PMT influences the processed signal intensity and the compensation matrix in a flow cytometer saves time and effort. We want to show

- how to characterize the gain of a given PMT (fluorescence channel) in order to define SPE per digital channel
- how to use the quantiFlash to optimize the compensation matrix

With this knowledge, the compensation matrix can be transferred without any further measurements to a new set of PMT voltages if a signal goes out of range in a certain channel.

PMT Characterization

Characterization of the spectral sensitivity of PMTs with quantiFlash and a monochromator
